

GenXR Watch

ISSUE 0.1 / EDITORIAL PREVIEW

What can you build now?

New tools, emerging capabilities, and the obstacles between an idea and a useful spatial experience.

AVAILABLE NOW / TOOL SPOTLIGHT

Describe a place. Explore it.

Marble turns prompts and visual references into explorable 3D environments. What can a non-programmer build with it? **Inside: page 2.**

EARLY ACCESS / 1 SEPTEMBER

Atlas aims beyond the still scene

World Labs' new model combines world generation, reconstruction and simulation. Selected partners can request access. Why watch it? More control over viewpoints could make spatial content easier to direct. **Inside: page 3.**

RESEARCH / PAPER: 1 OCTOBER

Worlds that remember your actions

Oneira, developed by Xindi Yang and colleagues, records objects and action outcomes so generated scenes retain changes. That could help training scenarios remain consistent. These are research findings; dependable headset use is not established.

RESEARCH CODE / PAPER: 1 OCTOBER

A room scan with working parts

LiteReality-Agent reconstructs rooms from colour-and-depth scans with articulated objects. The software was announced earlier; the October paper reports the research. Public code and a capture app require technical setup.

RESEARCH / PAPER: 1 OCTOBER

What happens when you look away?

World Observer, by Hyunwook Choi and colleagues, uses additional panoramic views to track activity outside an agent's current view. The aim is continuity when the agent returns: an important obstacle for credible simulations.

MARBLE / AVAILABLE NOW / PUBLIC RELEASE: 12 NOVEMBER 2025

From an idea to a place you can explore

For people with a spatial concept and no modelling skills, a first environment is becoming easier to create.

Reference image from World Labs' multi-image Marble demonstration. The company uses views of this courtyard to guide world generation. Image: World Labs.

Why it matters. An exhibition designer or educator may want colleagues to experience an idea before commissioning production. Marble, World Labs' browser-based world-generation tool, provides a starting point: describe a setting or upload visual references to generate a 3D environment. [1,2]

What you can do. Explore the result, revise its appearance, expand the space, and share or export it. World Labs also offers tools for combining worlds. These are creation capabilities; their usefulness still depends on your intended experience. [1,2]

A possible user journey. Start with a courtyard for a heritage exhibition. Provide references, generate a draft, inspect different viewpoints, and revise the atmosphere or layout. Invite feedback on the concept before developing the finished visitor experience. This is an illustrative workflow, not an independently tested museum deployment.

Where the work continues. An attractive environment is one part of an experience. If visitors must handle artefacts, operate equipment or complete assessed tasks, check how those behaviours will be added and tested. Do not assume that exporting a scene supplies the interaction design.

Accuracy needs evidence. Marble invents details absent from the input. For heritage interpretation, mark conjectural elements. For spatial planning, verify dimensions and object placement rather than trusting visual plausibility. A convincing scene is not evidence of a validated digital twin. [2]

Before committing. Check subscription limits, commercial-use terms and export options. Test the intended headset and sharing workflow with a small sample. Generation can begin without coding; deployment requirements depend on the destination and task.

Editorial verdict. A useful candidate for spatial concept exploration. Judge it against the next step in your project, including the work still needed to turn the setting into a usable experience.

Editorial implications are proposed uses. Product capabilities are company-reported; no hands-on test was conducted for this preview.

ATLAS / SELECTED-PARTNER EARLY ACCESS / ANNOUNCED: 1 SEPTEMBER 2026

More control over the worlds AI creates

World Labs' next model points toward more controllable spatial creation. Access and application readiness remain separate questions.

Poster from World Labs' Atlas demonstration reel, covering generated worlds, reconstruction and simulation. Company demonstration; not an independently tested outcome. Image: World Labs.

Why it matters. A curator or designer needs control over what audiences see as they move through a space. Atlas, World Labs' next-generation world model, aims to make generated viewpoints more consistent with supplied images and camera positions. It also reconstructs 3D scenes and models change over time. [3]

What is new. Announced on 1 September, Atlas combines these capabilities in one model. World Labs demonstrates camera-directed views, reconstruction from photographs, and simulation workflows. The company says Atlas will power future Marble versions; this does not mean every demonstrated capability is already in the public tool. [3]

A potential application. A heritage team could explore new viewpoints of a recorded location, or plan a visual journey through a proposed environment. The attraction is control: the team specifies viewpoints and supplies evidence instead of relying entirely on a broad text description. These are prospective uses requiring application-level validation.

The central limitation. Atlas fills unseen regions with plausible content. More photographs provide more evidence, but a generated view should not automatically be treated as a faithful record. For a museum or engineering project, identify which elements were observed and which were inferred. [3]

Can you use it today? The official announcement offers early access to selected partners through an application. That is a different proposition from signing up for a public creation tool. No general availability date is stated there. [3]

What to watch next. Look for an accessible interface, clear costs and a reproducible route from input images to the intended experience. For immersive use, ask about headset performance and supported interactions. For reconstruction, ask how errors are measured and how uncertain regions are identified.

Editorial verdict. A development worth following for control and reconstruction. Keep it on the opportunity horizon while assessing currently accessible software for immediate projects.
